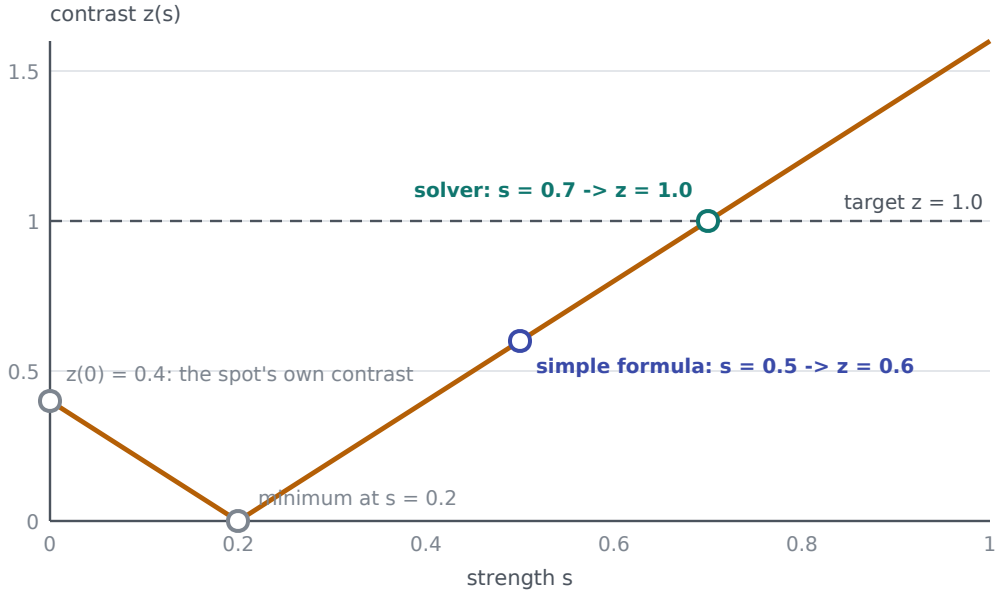
Solving on the realised contrast: one band, r = 0.20, sigma = 0.05, o0 = 0.22, step = -0.10



z(s) = mean |o0 + s x step - r| / mean sigma

The implant first cancels the spot's natural +0.02, then overshoots it.

The LLD's s = z x mean(sigma) / mean|step| assumes o0 = r, and lands in the wrong tier.

Rules in solve_strength:

- answer: first crossing at or after the minimum
- z(0) above the target: None, try another spot
- material out of reach at f = 1: capped, recorded
